

Elevator Pitch

Hello, my name is **[Placeholder]**, and I am one of the founders of SunPark.

We turn commercial parking lots into solar power plants. Businesses benefitting from this pay nothing upfront, and simply buy the electricity we generate at a cheaper rate than the grid. We own the asset, run it, and collect the revenue for 20 years.

Morocco has over a thousand commercial sites ready for change, and just passed a law making it legally possible for the first time. We are raising £420,000 to launch our first pilot and prove the model.

Could I show you in 15 minutes how one Moroccan car park becomes the validation for national solar rollout?

Teaser

SunPark

Solar Car Port as a Service

Turning wasted sunlight into clean energy infrastructure across Morocco’s commercial sector.

The Problem

Morocco’s commercial car parks are located in some of the strongest solar irradiance in the world, whilst generating nothing. At the same time, businesses pay over £0.086 per kWh to a grid whose tariff has risen 15% since 2023. Solar saves money, but businesses have the appetite in owning, financing, and maintaining the infrastructure, especially on sites they do not own.

That is the gap, and 18-21, Morocco’s new energy distribution generation framework, has made it legal for the first time.

Business Overview

SunPark finances, builds, owns and operates modular solar canopies over commercial parking lots. Clients pay nothing upfront. They sign a Power Purchase Agreement over the course of 20 years, of which they access energy as a significant cost reduction. We own the asset, carry all the risk, and collect the recurring energy revenue for the duration of the contract term.

1. High-Level Overview of the Proposition

Morocco sits at a structural inflection point in its energy transition. For the first time, Law 82-21 (2023) established a coherent legal framework for distributed self-generation under third-party Power Purchase Agreements (PPAs), while installations below 5 MW benefit from simplified licensing procedures. Simultaneously, commercial electricity tariffs have risen to approximately £0.086/kWh, with VAT on grid electricity increasing to 20% from 2026 under the Finance Act. These economic and regulatory shifts coincide with Morocco's national objective of achieving 52% installed renewable capacity by 2030 and the launch of initiatives such as the Morocco-Switzerland SR500 programme targeting 500 MW of commercial and industrial solar capacity. Despite these favourable conditions, commercial adoption remains limited because financing, ownership, and contractual barriers continue to prevent businesses from investing in solar infrastructure.

SunPark addresses this gap through a Solar Carport as a Service (SCaaS) model. The company finances, builds, owns and operates modular solar canopies installed over commercial parking facilities, selling generated electricity directly to site hosts under twenty-year PPAs at £0.069/kWh. Customers incur no upfront capital expenditure, assume no operational responsibility and avoid generation-performance risk. By transforming solar adoption from an asset-purchase decision into a long-term energy

procurement decision, the model removes the primary barriers that have historically constrained adoption within Morocco's commercial segment.

The addressable market consists of approximately 1,000 viable commercial sites across Morocco's retail, logistics, hospitality, and office sectors, representing an estimated £260 million installation opportunity. Market sizing is presented in British Pounds for consistency with investor materials and academic reporting; underlying assumptions are converted from Moroccan Dirhams using a constant exchange rate, with sensitivity testing conducted separately to account for currency risk associated with imported equipment. While uncertainty remains regarding the speed of regulatory implementation and customer adoption, SunPark's growth strategy prioritises disciplined portfolio development rather than aggressive market capture. The initial objective is a 50-site portfolio capable of generating approximately £4.25 million in annual recurring revenue through reference-led expansion, whereby a successful installation within a retail or logistics chain creates a credible pathway to subsequent deployments across the customer's wider property portfolio.

The venture's organisational design reflects the requirements of infrastructure entrepreneurship. Research on resource orchestration suggests that execution capability is often a more important determinant of venture success than technological innovation alone. Accordingly, SunPark's five-person founding team is structured around ownership of the venture's critical-path risks: commercial access, capital formation, technical delivery, regulatory execution and strategic partnerships. This alignment

between organisational capability and operational requirements reduces execution risk while supporting scalable growth.

SunPark is seeking £420,000 through a convertible note with a £2.6 million valuation cap and a 20% discount. The capital will fund regulatory preparation, commercial development, technical feasibility work and the equity contribution required for the first project Special Purpose Vehicle. Together with associated green-bank debt financing, the round is expected to deliver a fully operational pilot site in Agadir, secure follow-on customer commitments, and establish the contractual, regulatory and operational foundations required for a Series A financing round within eighteen months.

6. Traction

SunPark's traction at this stage is validation traction. We have not yet generated revenue. What we have is twelve months of structured market evidence demonstrating that the problem is real, the opportunity is unoccupied and our model addresses the specific failure modes that have caused others to abandon this segment.

Signal 1: Market Discovery

Over twelve months of expert-led primary research in Morocco, including direct engagement with retail operators, EPC contractors, ONEE-adjacent contacts, energy consultants, and industry practitioners, we identified zero structured retail Energy-as-a-Service providers operating in the Moroccan commercial segment. Adjacent players such as local EPC installers selling hardware, industrial PPA providers

serving single large offtakers exist but none combine PPA financing, retail-specific contracts, multi-site rollout frameworks, full operations and maintenance and the capability to operate on leased commercial property. This absence has been independently verified through desk searches of Moroccan business registers and renewable energy sector reports.

Signal 2: Failure Mode Discovery

Real-world project attempts in Morocco's retail solar segment have revealed three structural blockers, repeatedly: ROI mismatch (retailers expect 3-5 year payback against solar's 7-10 year reality), split ownership between leasing tenant and property landlord, and the absence of any standardised PPA contract structure for retail-grade installations. SunPark's business model was designed specifically to dissolve each of these three blockers through asset financing that removes the retailer payback question entirely, through a contractual structure that operates on leased premises, and through a standardised PPA template that replaces every bespoke negotiation. The model is the answer to the documented failure pattern.

Signal 3: Pilot site identified

A logistics warehouse in Agadir, accessed through a direct team relationship, is actively exploring photovoltaic installation and is committed as our reference site candidate. We acknowledge transparently that this is a related-party arrangement: it de-risks pilot execution and proves operational capability, but it does not yet validate arm's-length

commercial demand. Securing one independent customer Letter of Intent before Series A is our explicit next-milestone validation task.

Signal 4: Policy and capital tailwinds

Law 82-21 (2023) provides the legal foundation, the Morocco-Switzerland SR500 programme provides the strategic pull, and the IFC-Crédit du Maroc green SME lending facility (announced 2024, \$100M) provides a credible pathway to project debt once the first PPA is signed. The institutional environment is converging on SunPark's segment.

11. Research Supporting the Business Plan

Research Philosophy and Methodological Approach

The primary research programme consisted of more than a dozen semi-structured engagements conducted across Morocco's commercial energy ecosystem, including retail operators, EPC contractors, energy consultants, regulatory contacts, and infrastructure practitioners. In addition, the team undertook direct assessment of a logistics facility in Agadir that is being evaluated as the venture's pilot site. The objective of this research was not to quantify market demand but to understand the operational, contractual, and financial barriers preventing commercial solar adoption within the target segment.

This methodology is informed by Sarasvathy's (2001) theory of effectuation, which argues that entrepreneurial opportunities are often discovered through interaction and experimentation rather than identified through complete market information. In emerging sectors, entrepreneurs frequently operate under conditions of uncertainty rather than calculable risk, making iterative learning an essential component of opportunity evaluation. Rather than relying solely on market reports and industry forecasts, SunPark's understanding of the opportunity emerged through direct engagement with stakeholders and the practical investigation of potential solar projects in Morocco.

Primary Research

The primary research programme consisted of twelve months of engagement with stakeholders across Morocco's commercial energy ecosystem. Discussions were conducted with retail operators, EPC contractors, energy consultants, regulatory contacts, and infrastructure practitioners. In addition, the team undertook direct assessment of a logistics facility in Agadir that is being evaluated as the venture's pilot site.

The principal contribution of this research was not demand validation but problem validation. Across stakeholder groups, three recurring barriers consistently emerged: a mismatch between retailer investment expectations and solar payback periods, ownership fragmentation between landlords and tenants, and the absence of standardised contractual structures for retail-scale PPAs. These findings shaped the

venture's business model design and informed both the financial and contractual architecture presented throughout the business plan.

Nevertheless, limitations remain. The sample size remains relatively small and is concentrated primarily in Agadir and Casablanca. Discussions were qualitative in nature and therefore provide depth of insight rather than statistical generalisability. Furthermore, the venture has not yet conducted a formal survey capable of quantifying demand across the broader Moroccan commercial market. Consequently, the primary research should be interpreted as exploratory rather than conclusive.

Secondary Research

Secondary research was used to validate assumptions emerging from primary engagement and to provide quantitative support for market sizing, regulatory analysis, technical feasibility, and financial modelling.

Regulatory analysis draws primarily on the official text of Law 82-21, ONEE publications, and strategic planning documents issued by Morocco's Ministry of Energy Transition. Market sizing was developed through a bottom-up methodology using commercial property databases and satellite imagery to identify parking infrastructure suitable for solar carport deployment. Technical assumptions regarding irradiance, generation yields, and system performance were sourced from IRENA, the International Energy Agency, and NASA Surface Meteorology and Solar Energy datasets. Macroeconomic and tariff assumptions were cross-checked using ONEE tariff schedules, government publications, and international energy pricing databases.

Financing assumptions were informed through disclosures published by IFC, AfDB, and Moroccan financial institutions active in green lending programmes.

Although these sources provide a robust evidence base, several limitations must be acknowledged. Commercial property datasets may underrepresent informal developments and therefore generate conservative estimates of market size. Regulatory publications provide clarity regarding legislative intent but offer limited evidence regarding implementation speed. Similarly, international benchmarks on solar deployment costs may not fully reflect local procurement conditions within Morocco. For these reasons, no material quantitative claim was accepted into the business plan unless supported by at least two independent source categories.

Research Quality and Validation

To strengthen reliability, the research process employed triangulation across three evidence categories: official sources, industry sources, and primary stakeholder engagement. Quantitative assumptions were incorporated only when multiple sources converged on a similar conclusion. This approach reduces dependence on any single dataset while improving confidence in the resulting analysis.

However, four critical validation gaps remain. First, the venture has not yet secured an arm's-length commercial Letter of Intent from an independent customer. Second, no lender has issued a formal indicative term sheet for project financing. Third, EPC pricing assumptions have not yet been tested through a live competitive procurement process.

Finally, regulatory timelines under Law 82-21 remain based on consultation and expert estimates rather than completed commercial precedents.

These limitations do not invalidate the opportunity; rather, they define the venture's immediate validation agenda. Accordingly, the first six months following funding are structured not only as an execution programme but also as a research programme designed to convert key assumptions into verified evidence before significant scaling capital is deployed.

12. Implementation Plan and Team

Team Architecture

Entrepreneurship research highlights the importance of complementary human capital in ventures operating within complex and resource-intensive environments. Infrastructure businesses differ fundamentally from software startups because success depends on the coordinated execution of technical, financial, regulatory, and commercial activities over extended time horizons. As a result, venture performance is often constrained by the weakest critical capability rather than the strength of any individual founder.

SunPark's organisational structure has therefore been designed around ownership of critical-path risks rather than traditional functional departments. Each founder is responsible for a capability area that directly determines venture viability. Youssef leads commercial development and PPA negotiations, leveraging local market access and

stakeholder relationships to secure customers. Fariha oversees financial modelling, capital raising, and SPV architecture, ensuring projects remain bankable and scalable. Akilesh leads technical feasibility, system design, and EPC oversight, providing engineering credibility and delivery assurance. Sybil manages regulatory engagement, operational systems, and stakeholder coordination, while Ahmad leads strategic partnerships, investor engagement, and regional growth initiatives.

This structure reflects the resource orchestration perspective of entrepreneurship, which emphasises the entrepreneur's role in coordinating diverse resources into a coherent system capable of generating value. Rather than concentrating authority around a single founder, responsibility is distributed according to capability, improving accountability while reducing execution bottlenecks.

Advisor and Specialist Support

The venture supplements founder capabilities through a lean network of contracted specialists. Moroccan legal counsel supports regulatory filings and PPA development, while engineering, tax, and project finance advisors provide expertise in areas requiring specialist knowledge. This model enables access to specialist expertise without imposing the fixed-cost burden associated with full-time hires during the pre-seed stage. It also supports risk mitigation by allowing the venture to engage experienced counterparties where execution quality is critical, particularly in legal structuring, project finance, and engineering oversight.

Implementation Roadmap

The implementation roadmap is intentionally sequenced to reduce risk before significant capital deployment. Rather than prioritising rapid installation, the venture focuses first on establishing the contractual, regulatory, and financing foundations required for repeatable portfolio expansion. This sequencing reflects the reality that infrastructure ventures typically fail because of regulatory, financing, or commercial bottlenecks rather than technical shortcomings.

Phase 1 (Months 0–2) focuses on organisational establishment, legal structuring, and completion of the convertible note financing. Success is measured through entity registration, legal engagement, and capital receipt.

Phase 2 (Months 2–4) centres on regulatory preparation and stakeholder engagement. Activities include ONEE consultation, submission of required documentation under Law 82-21, development of the standardised PPA framework, and initiation of green-finance discussions. Progression beyond this phase depends on regulatory clarity and contractual readiness.

Phase 3 (Months 4–6) validates technical and commercial assumptions through completion of feasibility studies, EPC contractor selection, pilot-site commitment, and establishment of the first project SPV. The objective is to convert conceptual feasibility into executable infrastructure development.

Phase 4 (Months 6–12) involves construction and commissioning of the pilot installation. Delivery risk is mitigated through the selection of experienced EPC contractors operating under performance-based contractual arrangements and equipment

warranties consistent with industry standards. During this period, operational data, customer outcomes, and financial performance are collected to create a reference asset capable of supporting broader market adoption. Parallel business-development activity aims to secure follow-on Letters of Intent before the pilot reaches full operational maturity.

Phase 5 (Months 12–18) focuses on scaling. Pilot performance is leveraged to secure project debt, complete a Series A financing round, and expand the portfolio to four operational sites. At this stage, the venture transitions from proving the business model to demonstrating the repeatability of the platform. The pilot site's operating history is expected to improve access to non-dilutive project financing and infrastructure-focused capital, reducing reliance on founder-funded SPV equity as the portfolio expands.

Critical Execution Risks

The implementation sequence is designed to address the venture's two most significant execution risks: regulatory delay and customer acquisition speed. Regulatory uncertainty is mitigated through early engagement with advisors and authorities, ensuring approvals progress in parallel with technical development. Customer acquisition risk is mitigated by commencing commercial outreach before pilot completion, allowing relationship development and pipeline generation to occur simultaneously with construction activities. Together, these measures reduce the likelihood that operational readiness will outpace market readiness, a common challenge in early-stage infrastructure ventures.

-

Section-by-section

1. High-level overview of the proposition — 400 words

Owner: TBD

Must cover:

- Structural inflection: Law 82-21 (2023) + rising tariffs + 52% renewables target by 2030
- What SunPark is in one sentence (Solar Carport as a Service)
- The SCaaS model: fund, build, own, run modular solar canopies over commercial parking; clients pay zero upfront at £0.069/kWh under 20-year PPA
- Market sizing: ~1,000 viable commercial sites, ~£260M TAM
- Team's defining edge in one sentence (5 founders, each owning one critical-path risk)
- The ask: £420K convertible note (£2.6M cap, 20% discount) — £341K company capital + £79K site-level SPV equity triggering £184K green-bank debt

- What the round buys: first pilot live, two follow-on sites secured, rollout capital ready, Series A readiness within 18 months

2. Problem description — 700 words

Owner: Youssef

Must cover:

- Opening paradox: Morocco has the sun, the policy, the rising tariffs — yet minimal commercial retail solar
- Problem 1 — Import dependency: ~90% of energy imported; oil shock exposure (MDPI/Resources 2024)
- Problem 2 — Rising commercial costs: £0.086/kWh by late 2025, VAT to 20% in 2026 under Finance Act
- Problem 3 — The capex wall: operators don't want to own, finance or maintain energy infrastructure; split ownership tenant/landlord
- Why has this persisted: Law 82-21 only passed 2023, EPC firms focused on industrial deals, no player has built the multi-site retail model
- **Theory anchor (~80 words):** Apply Shane & Venkataraman (2000) Opportunity Recognition Theory — the regulatory change created an objective opportunity but required subjective recognition through prior knowledge and information asymmetries; 12 months of direct market testing is the recognition mechanism

Visuals:

- Figure 2.1: Problem tree diagram (regulatory / commercial / financial branches)
- Figure 2.2: Commercial electricity tariff trajectory 2018–2026
- Table 2.1: Ownership matrix (who owns roof, who pays bill, who has authority)

3. Sector analysis including forward-looking outlook — 1,250 words

Owner: Akilesh

Must cover:

Macro context (~300 words)

- Morocco's strategic position: no oil/gas, extraordinary irradiance, 20+ years of royal commitment to renewables
- 52% renewable capacity target by 2030, 70% aspirational by 2050
- NOOR complex (~580 MW) as proof of state capital deployment

- Distributed commercial generation as the explicit missing leg

Regulatory environment (~300 words)

- Law 82-21 (2023): self-generation framework, simplified licensing under 5 MW, surplus injection rights, third-party PPA basis
- ONEE's monopoly: friction but also barrier to foreign competitors
- SR500 programme: Morocco-Switzerland 500 MW C&I target by 2030
- Forward signals: draft amendments under consultation

Market sizing and outlook (~400 words)

- Bottom-up: 4,500 commercial premises → 1,800 with parking → ~1,000 viable
- £260K per carport × 1,000 = ~£260M TAM
- Morocco solar CAGR ~18.9% (IRENA 2024)
- Three scenarios for 2026–2030: base (15% of additions), upside (25%+), downside (sub-8%)

Theory anchors (~250 words combined)

- **Institutional Theory (DiMaggio & Powell 1983, ~100 words):** Law 82-21 = coercive institutional change; SR500 = normative pressure; early movers establishing mimetic adoption references
- **Energy Transition / Multi-Level Perspective (Geels 2002, ~80 words):** Morocco's transition operating at landscape (climate, energy security), regime (ONEE-dominated grid), and niche (distributed solar) levels; SunPark at the niche-regime interface
- Conclude with the strategic implication: SunPark is positioned at the convergence of three institutional pressures

Visuals:

- Figure 3.1: PESTEL analysis table (six dimensions × SunPark implications)
- Figure 3.2: Morocco solar capacity additions chart (historical + 3-scenario projection)
- Figure 3.3: Regulatory timeline (pre-2023 → Law 82-21 → future amendments)
- Table 3.1: Market sizing waterfall (4,500 → 1,000)

4. Detailed solution description — 850 words

Owner: Youssef

Must cover:

The proposition (~150 words)

- SCaaS model with expanded paragraph per "moving part" (deck framing): build & own, generate & sell, EV-charging ready, no land/no zoning
- Reinforce the three headline figures: £0 upfront, £0.069/kWh below £0.086 grid, 20-year contracted PPA

Technical architecture (~250 words)

- Steel-frame modular solar canopy structure
- Tier-1 monocrystalline PV (~300 kWp typical 200-space carport)
- String inverters, behind-the-meter grid connection
- Remote monitoring and SCADA, EV charging (Level 2/3 ready)
- Morocco-specific: dust mitigation, thermal performance, wind loads
- SunPark's role: system design and EPC oversight, not construction

Contractual architecture (~200 words)

- 20-year PPA, take-or-pay structure
- £0.069/kWh base, CPI-indexed with modest annual escalator
- Performance guarantees from SunPark
- Optional asset transfer at term end
- SPV structure isolating each site or portfolio
- The standardised PPA template as the single most important contractual asset

Operational architecture (~170 words)

- Three layers: asset O&M, performance monitoring, commercial relationship
- Customer experience: monthly MAD billing, real-time dashboard, annual sustainability reporting

Theory anchor (~80 words)

- **Business Model Innovation (Chesbrough 2010):** the technical artefact (carport) is not novel; the innovation is in value creation (bundled financing + ownership + O&M), delivery (multi-site standardised contracts), and capture (long-term recurring revenue). Schumpeterian innovation in the *combination* category

Visuals:

- Figure 4.1: Value Proposition Canvas (mandatory, Marketing module framework)
- Figure 4.2: Technical system schematic
- Figure 4.3: PPA contract structure diagram (cashflows and obligations)
- Figure 4.4: Customer journey timeline (first contact through 20-year PPA)

5. Business model description — 870 words

Owner: Ahmad

Must cover:

Build. Sell. Collect. framework (~150 words)

- Use the deck's three-step framing: Build & own (SunPark funds capex, client never appears on balance sheet) → Sell cheaper power (£0.069/kWh below £0.086 commercial grid) → Collect recurring revenue (20-year contract, asset-backed income)
- Why PPA over alternatives: Sell & install = one-time revenue with client risk; Lease = client carries weather risk; PPA = no capex, no generation risk, predictable savings

Business Model Canvas walkthrough (~150 words)

- All nine blocks in narrative before presenting visual

Revenue model (~150 words)

- PPA tariff with annual escalator
- ~£87K/year per site (1.25M kWh × £0.069)
- 20-year revenue per site: ~£1.7M nominal
- Secondary revenue: EV charging, RECs, carbon credits

Cost structure and unit economics (~220 words)

- Per-site installation cost: £260K (as per deck)
- Per-site annual opex: ~£12K (O&M, insurance, monitoring, central allocation)
- Gross profit per site: ~£75K/year (consistent with deck framing of 86% gross margin)
- **Critical clarification:** deck shows gross margin; written portfolio should also present EBITDA after corporate allocations to give a more complete picture. EBITDA per site after central overhead allocation: ~£55–65K
- Project finance: 70% debt at 8%, 30% equity at site level
- Unlevered IRR ~18–22%, levered IRR ~25–28%, payback ~7 years

Capital architecture (~200 words)

- Three-tier: corporate capital → SPV equity → project debt
- £420K convertible at corporate level (£341K company capital + £79K SPV equity)
- £79K site-level SPV equity triggers £184K green-bank debt = £263K available for first installation
- 70% green bank debt against PPA cashflows
- Evolution to portfolio-level institutional capital at Series A+

Theory anchors (~100 words combined)

- **Resource-Based View (Barney 1991, ~60 words):** competitive advantage from VRIN resources — standardised PPA template, primary market research, first-mover regulatory relationships, pilot reference asset
- **Dynamic Capabilities (Teece 2007, ~40 words):** SunPark must demonstrate sensing (market intelligence), seizing (operational execution), and transforming (capability additions in product roadmap)

Visuals:

- Figure 5.1: Business Model Canvas (mandatory, all nine blocks)
- Figure 5.2: Per-site unit economics table
- Figure 5.3: Capital stack diagram (£341K company + £79K SPV + £184K green debt)
- Figure 5.4: 20-year cumulative cash flow per site

6. Traction — 400 words

Owner: Fariha

Must cover (~100 words each):

- Signal 1 — Market discovery: 12+ months of expert-led market discovery in Morocco; zero structured retail EaaS providers identified
- Signal 2 — Failure mode discovery: real-world testing revealed three blockers repeatedly — ROI mismatch, split ownership, no standardised contract structure. SunPark's model targets exactly those three blockers by design
- Signal 3 — Pilot site identified: an Agadir logistics warehouse, via a direct team relationship, is exploring PV. Honestly flag as related party; next milestone is independent customer LOI before Series A
- Signal 4 — Policy tailwind: Law 82-21 and the SR500 programme back self-generation at scale; IFC-Crédit du Maroc facility provides debt capital pathway

Be precise: these are validation signals, not commercial traction.

Visuals:

- Figure 6.1: Validation timeline (12-month research journey)
- Table 6.1: Traction signals matrix (what we have / what we lack / next milestone)

Visuals:

- Figure 8.1: Portfolio roadmap timeline (4 stages with site count, ARR, capabilities, capital triggers) — mirror the deck's portfolio path visualisation

- Figure 8.2: Capability stack diagram (core PPA + modular layers)

7. Initial development plan — 550 words

Owner: Sybil

Must cover:

Workstream overview (~100 words)

- Five parallel workstreams across Months 0–6: legal, regulatory, technical, financial, commercial
- Gate at Month 6: pilot site locked, EPC selected, ready for installation

Phase-by-phase detail (~350 words)

- **Foundation (M0–2):** Register company, appoint counsel, draft PPA template, convertible note close
- **Regulatory (M2–4):** Government approvals, ONEE grid sign-off, regulatory filings
- **Pilot (M4–6):** Feasibility study complete, pick builder, lock pilot site, financial close on first SPV

Critical path (~100 words)

- ONEE grid pre-approval (8–12 week dependency) and PPA template finalisation as bottlenecks
- Convertible note timing as lateral risk affecting all downstream activities

Visuals:

- Figure 7.1: 6-month Gantt chart
- Figure 7.2: Dependency diagram

8. Product roadmap — 550 words

Owner: Sybil

Must cover:

Portfolio progression stages — match deck precisely (~270 words)

- **Stage 1: Pilot (M0–12):** 1 site, Agadir, ~300 kWp
- **Stage 2: Breakeven (4 sites, £340K):** anchor chain signed, multi-site framework proven

- **Stage 3: Series A ready (20 sites, £1.7M ARR):** reference-led expansion across 3–4 chains, geographic spread to Rabat/Tangier/Marrakech
- **Stage 4: Exit ready (50+ sites, £4.25M+ ARR):** infra-fund acquisition target, MENA expansion

Capability additions (~130 words)

- EV charging integration (Stage 2): future-proofed at install per deck framing
- Battery storage (Stage 3): +£80K capex, grid services + peak shaving
- Energy management SaaS (Stage 3): +£3K/year per site
- REC monetisation (Stage 2+): +£8K/year per site at maturity
- Carbon credit certification (Stage 3): +£5K/year

Sustainability as strategic driver (~100 words)

- Customer-side drivers: Scope 2 emissions under GHG Protocol; EU CSRD compliance for Moroccan exporters' EU customers; rising carbon costs for any business with European trading relationships
- This converts sustainability from "nice-to-have" to strategic necessity for SunPark's customers

Exit thesis (~50 words)

- 50+ sites generating £4.25M+ ARR (per deck) × infrastructure multiple = ~£40–55M EV
- Buyer profile: infrastructure funds, utilities, IPPs

9. Competitive analysis — 900 words

Owner: Akilesh

Must cover:

Competitive landscape overview (~140 words)

- Four categories per deck: SunPark (the category), Local installer (50+ firms), Industrial PPA (bespoke deals), In-house/captive (few programs)
- No structured retail EaaS provider exists in segment — SunPark is the category

Detailed competitor analysis (~330 words)

- Local EPC installers (~50 firms, ~80 words): hardware-only, no PPA, no retail contracts, no multi-site, no full O&M, doesn't work on leased sites
- Industrial PPA providers (~80 words): has PPA financing and full O&M, but no retail contracts, no multi-site framework, doesn't work on leased sites

- **In-house/captive (~140 words):** most important to address; few known programmes; has retail contracts and multi-site capability but no PPA financing, no full O&M, doesn't work on leased sites; three reasons it's not a categorical threat: requires aligned retailer-REIT (rare), requires REIT to build solar capability (they don't want to), validates rather than destroys market
- Foreign EaaS entrants (~30 words): none active currently; future risk

Porter's Five Forces applied (~200 words)

- Threat of new entrants: medium-high; defence is first-mover + standardised contracts
- Bargaining power of suppliers: low; commoditised EPC and panels
- Bargaining power of buyers: medium; high switching costs once installed
- Threat of substitutes: low; grid is the substitute and getting more expensive
- Competitive rivalry: currently low, intensifies 2027–2030

Strategic positioning (~150 words)

- Reframe per deck: "Not a solar company. A retail energy contract company."
- SunPark wins on four dimensions: we solve ownership (work on leased sites), one contract many sites, zero risk for retailer, first-mover in Law 82-21

Theory anchor (~80 words)

- **Porter's Generic Strategies (1985):** SunPark pursues *focused differentiation* — narrow segment (commercial retail solar in Morocco) with differentiated value (PPA financing + standardised contracts + multi-site framework). Most defensible against larger entrants because it requires segment-specific knowledge that generalists lack

Visuals:

- Figure 9.1: Competitor comparison matrix (5 features × 4 categories) — replicate deck's matrix
- Figure 9.2: Porter's Five Forces diagram (Morocco-specific)
- Figure 9.3: Strategic positioning map

10. Financial forecast for minimum three years — 1,400 words

Owners: Ahmad + Youssef

Must cover:

Methodology and assumptions (~250 words)

- Three-year model: monthly Y1, quarterly Y2–3

- Driver-based: site additions, capex, tariff, escalator, opex, debt, overhead
- Reference unit economics from Section 5
- Every material assumption explicitly sourced (full register in Appendix B):
 - 20 sites by Year 3 (Series A ready) → from GTM conversion analysis (Section 13)
 - £0.069/kWh PPA → 20% below £0.086 grid (GlobalPetrolPrices.com)
 - 8% debt cost → IFC-Crédit du Maroc green facility benchmarks
 - 2.5% escalator → Morocco 5-year CPI average (HCP)
 - £260K capex per site → IRENA + EPC RFI triangulation
 - 1.25M kWh/year → NASA SSE irradiance + PVsyst methodology

P&L forecast (~300 words)

- Three-year summary table aligned to deck's portfolio path:
 - Y1: pilot live mid-year, partial revenue ~£40K
 - Y2: 4 sites operational (deck breakeven), revenue ~£340K
 - Y3: 20 sites operational (deck Series A ready), revenue ~£1.7M
- COGS, gross profit, opex, EBITDA, D&A, EBIT, interest, pre-tax
- Narrative: Y1–2 accounting losses funded by debt+SPV equity, not operating cash; EBITDA positive at Year 2 breakeven, scaling rapidly Year 3

Cash flow forecast (~300 words)

- Operating cash flows track EBITDA pattern
- Investing cash flows: site capex by year (£260K / £780K / £4,160K based on 1 → 4 → 20 sites)
- Financing: convertible note Y1, Series A M18, green bank drawdowns, debt service
- Cash trough at M18 explains funding timeline

Scenario analysis (~200 words)

- Base: 1/4/20 sites, matches deck portfolio path
- Downside: 1/3/12 sites, breakeven delayed to Y3, Series A delayed to M24
- Upside: 2/6/28 sites with grant capital, breakeven Y2 early

Sensitivity analysis (~200 words)

- Tornado chart: ±20% on installation cost, PPA tariff, customer acquisition timeline, O&M, MAD/GBP
- Identifies installation cost as highest-sensitivity variable

Funding requirement and cap table (~150 words)

- Convertible: £420K total (£341K company + £79K SPV equity), £2.6M cap, 20% discount → ~16% dilution at conversion
- Series A: ~£1.5M at Month 18, ~£8M post-money → ~19% additional dilution

- Founder ownership through Series A: ~65%
- £79K SPV equity unlocks £184K green-bank debt — explicit project finance leverage

Visuals:

- Figure 10.1: 3-year P&L summary chart aligned to portfolio milestones
 - Figure 10.2: Monthly cash position chart (36 months with capital events marked)
 - Figure 10.3: Three-scenario comparison
 - Figure 10.4: Sensitivity tornado chart
 - Figure 10.5: Cap table evolution
 - Figure 10.6: Per-site IRR/NPV summary (unlevered and levered)
-

11. Research supporting the business plan — 700 words

Owner: Fariha

Must cover:

Research methodology framework (~200 words)

- Mixed-methods design: primary qualitative (12-month Morocco market immersion) + secondary quantitative (regulatory documents, sector reports, satellite imagery for site counting)
- Triangulation across three source types: official (government, multilateral), industry (sector reports, EPC data), primary (advisor network)
- Connection to entrepreneurship literature on opportunity identification through bricolage and effectuation (Sarasvathy 2001) — knowledge developed through *doing* rather than only desk research

Primary research (~150 words)

- 12 months of advisor engagement with retailers, EPC contractors, ONEE contacts, energy consultants
- Direct Agadir site assessment
- May 2026 pitch outreach (cite any LOIs or expressions of interest secured)
- Honest limitations: small primary sample, geographic concentration, no quantitative customer survey

Secondary research (~150 words)

- Regulatory: official Law 82-21 text, ONEE reports, Ministry plans
- Market sizing: bottom-up via property registers + satellite validation
- Tariff data: GlobalPetrolPrices, ONEE, Finance Act 2024
- Technical: IRENA, IEA, NASA SSE

- Competitive: business registers, Moroccan sector reports
- Capital: IFC, AfDB, Crédit du Maroc

Source evaluation matrix (~100 words)

- Table assessing each source category on credibility (high/medium/low), recency, independence

Validation gaps and next steps (~100 words)

- Not yet validated: arm's-length customer LOI, formal green bank term sheet, competitive EPC pricing, ONEE process timelines
- All four are M0–6 validation tasks

Visuals:

- Table 11.1: Source credibility matrix
- Appendix A: Full reference list (35+ Harvard sources)

12. Implementation plan + Team — 650 words

Owner: Fariha

Must cover:

Team architecture (~180 words) — match deck precisely

- Five founders, each owning one critical-path risk (deck framing: "An infrastructure business, not a pure software startup")
- **Youssef — Commercial & PPA:** Morocco commercial access, retailer relationships, PPA negotiations
- **Fariha — Finance & Capital:** financial model, capital structure, SPV architecture; makes each site investable
- **Akilesh — Technical & EPC:** technical feasibility, system sizing, EPC selection, delivery quality
- **Sybil — Ops & Regulatory:** operations, regulation, stakeholder coordination across rollout
- **Ahmad — Partnerships:** partnerships, investor access, regional expansion mapping
- Closing tagline from deck: "Turning wasted urban space into clean energy infrastructure — without asking customers to carry the upfront burden"

Advisor and contractor structure (~80 words)

- Moroccan legal counsel, solar engineering advisor, project finance advisor, tax advisor

- All contracted not hired — keeps burn lean while accessing expertise

18-month implementation roadmap — match deck (~340 words)

- **Phase 1 Foundation (M0–2):** Register company, appoint counsel, draft PPA
- **Phase 2 Regulatory (M2–4):** Government approvals, ONEE grid sign-off, filings
- **Phase 3 Pilot (M4–6):** Feasibility, pick builder, lock pilot site
- **Phase 4 Install (M6–12):** Build, commission, sign 2 follow-ons
- **Phase 5 Scale (M12–18):** Green-bank loan drawn, Series A, chains 2–4
- Gate criteria explicit at each phase transition

Critical execution risks (~50 words)

- ONEE delays mitigated by parallel-track advisor engagement
- Customer acquisition speed mitigated by warm-network outreach from M4

Visuals:

- Figure 12.1: Team structure diagram (5 founders × critical-path workstreams)
- Figure 12.2: 18-month implementation Gantt with 5 phases (mirror deck's timeline)
- Figure 12.3: Workstream ownership matrix

13. Go-to-market plan — 850 words

Owner: Sybil

Must cover:

Segmentation and prioritisation (~180 words)

- Four B2B segments per deck (retail, hospitality, offices, logistics): retail (largest, slowest 9–12 mo cycle), logistics (faster 4–6 mo, Agadir pilot here), hospitality (6–9 mo, smaller systems), office (4–6 mo)
- Prioritisation: logistics first, retail second, hospitality and office opportunistically

Beachhead strategy — match deck framing (~120 words)

- Deck framing: "Warm relationships first, starting with the Agadir pilot, then proof-led outreach to commercial decision-makers"
- Agadir pilot as single live operational reference (live by M12)
- Pre-pilot activity limited to relationship-building, not deal closure
- Post-pilot full commercial activation across prioritised segments

Channel strategy — match deck (~180 words)

- Direct enterprise sales (primary): targeted email and LinkedIn to commercial decision-makers
- Indirect referrals (secondary): EPC contractors, green lenders, energy consultants, legal advisors
- Industry presence (tertiary): Morocco Renewable Energy Week, MASEN events
- Budget allocation: 60% direct sales, 25% events/content, 15% referral

Sales cycle and conversion funnel (~140 words)

- Customer Acquisition Factory framework (Marketing module): awareness → interest → consideration → commitment → onboarding → reference
- Assumed conversion: 100 awareness contacts → 30 first meetings → 12 proposals → 4 LOIs → 2 signed PPAs per BD resource per year

Pricing strategy (~100 words)

- Base PPA at £0.069/kWh, below £0.086 grid benchmark
- Modest annual escalator (CPI-linked)
- Volume discount for multi-site chain commitments
- Philosophy: cheaper than grid every year regardless of grid movements

Theory anchor (~130 words)

- **Diffusion of Innovation (Rogers 1962):** customer segmentation maps to adopter categories — Agadir pilot owner is the *innovator* (related-party, high trust threshold acceptable), chains 2–4 are *early adopters* (looking for competitive advantage, willing to bear reference-customer risk), broader retail market is the *early majority* (require proven references and standardised contracts — exactly what SunPark builds for them). The GTM sequence is theoretically grounded adoption strategy, not just sales pipeline

Visuals:

- Figure 13.1: Customer acquisition factory diagram (with SunPark metrics)
- Figure 13.2: Sales cycle timeline by segment
- Figure 13.3: Customer journey map (awareness through 20-year PPA)
- Figure 13.4: Channel allocation pie chart

14. Marketing plan — 650 words

Owner: Youssef

Must cover:

Brand positioning — match deck (~150 words)

- Core position from deck: "Not a solar company. A retail energy contract company."
- Reframes evaluation from technology (panel efficiency) to commercial (reliability, financial strength, counterparty trust)
- Brand attributes: trusted, structured, asset-grade, Moroccan-built, sustainable
- Voice: confident, technically credible, commercially fluent
- Closing positioning from deck: "Solar becomes a simple commercial decision — not a complex infrastructure project"

CBBE pyramid applied (~200 words)

- Level 1 Salience: top-of-mind awareness via events, content, referrals; 70% segment awareness by Year 2
- Level 2 Performance and imagery: functional reliability + emotional professionalism
- Level 3 Judgements and feelings: credibility (financial strength, track record) + superiority (vs alternatives)
- Level 4 Resonance: behavioural loyalty (multi-site rollouts), attitudinal attachment (energy partner, not vendor)
- Year-by-year focus: Y1 awareness, Y2 performance/judgements, Y3 resonance

Marketing activities (~200 words)

- Reference development: Agadir pilot case study with measured outcomes published M9
- Content marketing: monthly LinkedIn thought leadership on Morocco renewables, regulation, PPA structuring
- Industry events: speaking slots at Morocco Renewable Energy Week, MENA Solar Conference
- Partnership communications: joint announcements with EPC, advisors, capital providers
- PR: Médias24 and L'Économiste targeted outreach at milestone moments
- Customer marketing: quarterly performance reviews, annual sustainability reports

Customer lifetime value (~100 words)

- CLV per chain (10 sites): £870K annual revenue, £750K contribution margin, 20-year contract, 95% retention, 10% discount
- NPV per chain: ~£6.3M
- CAC per chain: ~£25–30K
- LTV/CAC ratio: ~200×

Visuals:

- Figure 14.1: CBBE pyramid applied to SunPark
 - Figure 14.2: CLV calculation table
 - Figure 14.3: Marketing funnel (awareness → advocacy with metrics)
 - Figure 14.4: Y1 marketing activity calendar
-

15. Risk analysis — 750 words

Owner: Ahmad

Must cover:

Risk framework (~80 words)

- Probability × Impact assessment (Low / Medium / High)
- Each risk: probability, impact, mitigation, leading indicator, contingency
- Eight risks across seven categories

Risk register (~450 words, ~55 words per risk)

- Market risk — slower commercial adoption (P: Med, I: High)
- Regulatory risk — ONEE delays (P: Med, I: High)
- Operational risk — EPC failure (P: Low, I: High)
- Financial risk — green bank debt unavailable on assumed terms (P: Med, I: High)
- Competitive risk — foreign EaaS entrant (P: Med, I: Med)
- Team risk — co-founder departure (P: Low, I: Med)
- Macro risk — MAD depreciation (P: Med, I: Med)
- Reputational risk — pilot underperforms publicly (P: Low, I: High)

Risk heat map and prioritisation (~100 words)

- Plot all eight on probability × impact matrix
- Four risks in top-right quadrant are priority focus: commercial adoption, ONEE delays, green bank terms, EPC performance
- Quarterly risk review with investor governance reporting

Critical reflection: scenarios in which SunPark fails (~120 words)

- Honest engagement with three failure modes most likely to kill the business:
 1. Commercial adoption proves slower than even downside case because retail decision-making is more conservative than assumed
 2. In-house/captive model spreads faster than expected as REITs build solar capability
 3. Morocco political stability assumption proves wrong; capital flight raises cost of capital prohibitively
- This section visibly demonstrates Master's-level critical thinking by engaging rival interpretations rather than defending the thesis

Visuals:

- Figure 15.1: Risk heat map (probability × impact, all 8 risks plotted)
- Figure 15.2: Risk register table (8 risks × 5 attributes)

- Figure 15.3: Risk evolution chart (top 4 risks over M0–18)

Key consistency points with the deck

When drafting, ensure these specific numbers and framings appear identically across the portfolio:

Element	Value to use
TAM	~£260M installation opportunity
SAM	~1,000 commercial sites
SOM	50 sites, £4.25M+ ARR
PPA tariff	£0.069/kWh
Grid benchmark	£0.086/kWh
Per-site installation cost	£260K
Per-site annual revenue	~£87K
Per-site gross profit	~£75K
Per-site annual generation	1.25M kWh
Breakeven point	4 sites, £340K
Series A ready	20 sites, £1.7M ARR
Exit ready	50+ sites, £4.25M+ ARR
Total ask	£420K convertible
Company capital	£341K
Site-level SPV equity	£79K
Green-bank debt triggered	£184K

Convertible cap	£2.6M, 20% discount
Implementation timeline	18 months
Phases	Foundation (M0–2), Regulatory (M2–4), Pilot (M4–6), Install (M6–12), Scale (M12–18)

Required theoretical references (Appendix A)

Minimum 35 sources, including these core theoretical anchors:

15	Risk	Ahmad	750
Total			11,070

Trim 70 words during final edit to stay within the +10% cap.

Workload by team member

Member	Sections	Total words
Youssef	2, 4, 14, + half of 10	2,900
Akilesh	3, 9	2,150
Ahmad	5, 15, + half of 10	2,320
Fariha	6, 11, 12	2,150
Sybil	7, 8, 13	1,950

Three-week production timeline

Week 1 (3–9 June) — Structure and research

- Set up Word document with all 15 headers and word allocations
- Each member begins research and outlines their sections as bullet stubs
- Fariha begins financial model build in Excel

- Ahmad begins assumptions register (Appendix B)

Week 2 (10–16 June) — First drafts

- Each member writes their assigned sections to 70–80% of final length
- Fariha builds the financial model exports
- All visuals begun in parallel

Week 3 (17–19 June) — Integration, polish, submission

- Cross-section integration review (90 minutes minimum)
- All visuals finalised
- Executive summary
- Reference list compiled
- End-to-end read by two members
- Submit by 19 June 23:59

Quality checklist before submission

Verify:

- ☐ Every quantitative claim matches the deck numbers exactly (use the consistency table above)
- ☐ Every visual is numbered, captioned, and referenced in text
- ☐ Theoretical anchors are integrated analytically, not decoratively
- ☐ Financial scenarios match risk analysis (downside in financials = top-priority risks materialising)
- ☐ Team section maps to implementation workstreams
- ☐ Competitive analysis honestly addresses in-house/captive threat
- ☐ Traction section is transparent about related-party pilot
- ☐ Executive summary contains nothing not in body
- ☐ Word count between 9,500 and 11,000
- ☐ Consistent formatting throughout
- ☐ Harvard referencing throughout
- ☐ Two team members have read end to end for typos
- ☐ Appendix B (assumptions register) is complete
- ☐ All deck framings preserved ("Not a solar company. A retail energy contract company.", "Build. Sell. Collect.", "Turning wasted urban space into clean energy infrastructure")

Script Draft

Youssef walks in holding car keys and a sunshade.

Youssef: You know that moment when you come back to your car after it's been parked in the sun? . The handle is too hot. The seat is burning. The steering wheel is untouchable. So you do what everyone does. Holds up sunshade.? You fight with one of these. But step back for a second. What is actually happening? The sun is hitting this car park every single day. And right now, all that energy is wasted doing one thing: making cars unbearable.

SunPark changes that. We put solar canopies over commercial car parks. The cars get shade. The building gets cheaper electricity. And the owner pays nothing upfront. We finance, own, and maintain the system. The customer simply buys the electricity through a long-term contract. So a normal car park gets a second job. It still parks cars. But now, it also generates power. That is SunPark: turning wasted sunlight into clean electricity, customer comfort, and long-term energy assets. Transition: And now Ahmad will show why this is not just a clever idea, but a scalable market opportunity.

SLIDE 2 — Today

You know that moment when you come back to your car after it's been parked in the sun?

The handle is too hot. The seat is burning. The steering wheel feels illegal.

So you do what everyone does.

You fight with one of these.

SLIDE 3 — Problem

But step back for a second. What is actually happening?

The sun is hitting this car park every single day. And right now, all that energy is doing one thing: making cars unbearable.

SLIDE 4 — WITH SUNPARK

SunPark changes that.

We put solar canopies over commercial car parks. The cars get shade. The building gets cheaper electricity. And the owner pays nothing upfront.

SLIDE 5 — OUR SOLUTION

We finance, own, and maintain the system. The customer simply buys the electricity through a long-term contract.

So a normal car park gets a second job. It still parks cars. But now, it also generates power.

SLIDE 6 — ONE MODEL, FOUR MOVING PARTS

That is SunPark: turning wasted sunlight into clean electricity, customer comfort, and long-term energy assets.

And now Ahmad will show why this is not just a clever idea, but a scalable market opportunity.

Slide 6: Ahmad

What Youssef just showed is not one unusual car park. It is a repeatable pattern.

Across Morocco, our research found around 1,000 commercial sites with the same ingredients: strong sun, usable parking space, and rising demand for cheaper power.

At roughly £260,000 per carport, that is a £260 million installation opportunity.

But we do not need to win all of it to prove the business.

We start with one pilot in Agadir, then scale site by site toward a near-50-site portfolio.

So the story is simple: prove one car park, then repeat the model across a market that is hiding in plain sight.

Slide 7: Ahmad

And the reason it works that the customer decision is easy.

Today, they pay the grid.

With SunPark, they pay less, with no upfront investment

We build and own the carport. They buy the electricity.

Our base-case PPA tariff is around 7 pence per kilowatt-hour, below the grid benchmark of around 8.5 pence.

So the customer saves from day one, and sunpark earns recurring revenue for 20 years

Slide 8: Ahmad

One typical site produces around 1.25 million kilowatt-hours a year.

That creates about £87,000 in annual revenue

So one £260,000 installation can create roughly £2.2 million in contracted revenue over 20 years.

At near-50-site scale, that becomes around £4.2 million in ARR.

That is the engine of SunPark: each car park becomes a cash-generating infrastructure asset, and once one works, the next one becomes easier to finance, sell, and repeat.

Slide 9: Akilesh

Morocco has solar installers. That is not the gap.

Installers build systems, but usually leave the customer to fund and own them.

Industrial PPA providers focus on large bespoke projects.

In-house programmes require finance, legal, and technical capacity most retailers do not have.

In our research, we did not identify a provider combining all our capacities.

That gap is SunPark.

Slide 10: Akilesh

Our advantage is structure.

We combine financing, ownership, maintenance, regulatory support, and repeatable contracts.

That turns solar from a complex infrastructure project into a simple commercial decision.

One negotiation can become a rollout across multiple sites.

One customer can become a portfolio.

We solve the ownership problem that stops commercial solar projects from happening.

The customer gets cheaper power without capex or operational burden.

SunPark gets long-term contracted revenue from assets we own and operate.

Slide 12: Sybil

Our 18-month target is clear: first pilot live, two follow-on sites signed.

That takes us from concept to live asset, then from live asset to rollout.

We move in parallel: Legal setup, regulation, feasibility, EPC selection, financing, and customer acquisition all start early.

Our go-to-market is B2B enterprise sales.

We begin with warm personal relationships in Morocco, starting with the Agadir pilot site. Then we use that proof point to approach commercial decision-makers

We acquire customers through relationship-led introductions, targeted email and LinkedIn outreach, and referrals from EPC contractors, green lenders, energy consultants, and legal advisors.

That is the bridge from pilot to portfolio.

Slide 14: Fariha

This opportunity came from real market discovery.

After 12 months of expert-led research in Morocco, we identified the same blockers repeatedly: ROI mismatch, split ownership, and no standardised contract structure.

We also have a pilot site identified in Agadir through a direct team relationship.

That gives us a warm-start route to validate the model before scaling into retail carports.

Slide 15: Fariha

This team is built around execution risk, but also around impact.

As young founders, we believe clean energy cannot stay theoretical. It has to become practical, affordable, and easy for businesses to adopt.

That is what drives SunPark.

Each founder owns one critical part to make that happen

Youssef owns Morocco commercial access and PPA negotiations.

I lead the financial model and capital structure.

Akilesh owns technical feasibility and EPC delivery.

Sybil owns operations, regulation, and stakeholder coordination.

Ahmad owns partnerships, investor access, and expansion mapping.

So we are impact-driven, but execution-focused. And where specialist expertise is needed, we bring in legal, technical, and project-finance advisors

Slide 16: Fariha

We are raising £420,000 on a convertible note at a £2.6 million cap.

£341,000 funds company setup, approvals, BD, and feasibility, including regulatory contingency.

£79,000 goes into the first site SPV as equity, unlocking £184,000 of green-bank debt to fund the £260,000 first installation.

But we are not only asking for money.

We are asking for strategic access to Moroccan site owners, green infrastructure lenders, EPC partners, and energy and legal advisors.

That access helps us secure the pilot, finance it, build it, and prepare the rollout.

The goal is clear: pilot live, two follow-ons signed, and rollout capital ready.

Slide 17:

Thank you.

QnA

Q: "You are raising on a convertible note with a £2.6M cap. You have no revenue, no signed contracts, one warm lead, and five graduates. A £2.6M valuation cap implies that at Series A you expect the company to be worth at least £2.6M before the note converts. What is the specific methodology behind that cap — comparable transactions, DCF on projected cashflows, or a number chosen to make the dilution feel acceptable?"

A: "The £2.6M cap is derived from two inputs, not one. The first is a DCF on the contracted PPA cashflows at 50-site scale — which is our Series A trigger point. At 50 sites generating £75K net cash per site per year, portfolio gross cashflow is £3.75M annually. At a 6x EBITDA multiple — conservative for contracted infrastructure cashflows — that implies a portfolio value of £22.5M at exit. The Series A raise targets 20 sites, which is £1.5M annual cashflow, at 6x is £9M. A 20–25% stake sold at Series A implies a pre-money of approximately £27–36M at that stage. The convertible cap of £2.6M applies at Series A conversion, meaning seed note holders convert at the lower of the cap or the Series A price with a 20% discount. Given the projected Series A valuation, they will almost certainly convert at the cap — meaning our seed investors get shares at roughly a 10x discount to Series A price if we hit plan. That is the return profile we are offering. The second input is comparable transactions: pre-revenue solar EaaS companies in MENA and Sub-Saharan Africa have raised seed rounds at £1.5M–£3M caps in 2023–2025. We are in the middle of that range."

Q: "Your traction slide leads with the Agadir pilot as validation. But the Agadir site is a logistics warehouse. Your entire market, TAM, SAM, SOM, competition slide, and GTM are built around commercial retail — hypermarkets, shopping centres, retail parks. A logistics warehouse and a hypermarket are completely different customers with different energy profiles, different procurement structures, and different lease arrangements. Is your first site actually in your target market, or is it a convenient warm relationship that slightly misrepresents the traction you have?"

A: "That is a fair and precise challenge and we should address it directly. The Agadir warehouse is not a retail site — you are correct. We present it as a pilot validation site, not a target customer reference. Its purpose is narrow and specific: to prove the physical installation model, the ONEE grid connection process, and the O&M operating rhythm under Law 82-21 before we approach a retailer. The unit economics on a logistics warehouse are actually less favourable than retail because energy consumption is lower and less predictable — so if the model works there, it works more strongly in retail. The commercial validation — the proof that a retail procurement team will sign a PPA — comes from the anchor retailer conversations running in parallel from month zero. We are not waiting for the warehouse to be complete before approaching Marjane or Label'Vie. The warehouse proves the technical and regulatory model. The retail conversation proves the commercial model. We need both and we are running both simultaneously."

Q: "You're asking for £420K. Walk me through exactly how you got to that number."

A: "The ask has two parts. The first is £341K of company capital: a bottom-up budget of £270K covering team, legal, technical, commercial, SPV structuring and contingency, plus a £71K regulatory reserve

specifically for Moroccan approval timelines — Law 82-21 is new and ONEE approvals are untested at this scale. The second is £79K of pilot equity — the 30% we inject into the first site SPV. That £79K levers £184K of green-bank project debt at 8.5% over 15 years, secured against the solar asset, to fund the full £260K first installation. So the structure is: £341K runs the company for 18 months. £79K opens the first site. The bank funds the rest. Total: £420K."

Q: "You are raising on a convertible note with a £2.6M cap. You have no revenue, no signed contracts, one warm lead, and five graduates. A £2.6M valuation cap implies that at Series A you expect the company to be worth at least £2.6M before the note converts. What is the specific methodology behind that cap?"

A: "The £2.6M cap is anchored to the financial model, not chosen for optics. At 20 sites — our Series A trigger — portfolio revenue is approximately £1.7M annually at a conservative 4.5× revenue multiple, that implies a Series A valuation of around £7.7M. The convertible note converts at the lower of the cap or the Series A price — so our seed investors convert at £2.6M, which is well below the projected Series A valuation. That gap is their return for taking early risk. The £2.6M cap also sits within the range of pre-revenue solar EaaS seed rounds in MENA and Sub-Saharan Africa, which have closed at £1.5M to £3M caps in 2023 to 2025. We are in the middle of that range with a more detailed financial model than most at this stage."

Q: "Your traction slide leads with the Agadir pilot as validation. But Agadir is a logistics warehouse. Your entire market, TAM, SAM, SOM, and GTM are built around commercial retail. A logistics warehouse and a hypermarket are completely different customers. Is your first site actually in your target market, or is it a convenient warm relationship that slightly misrepresents your traction?"

A: "That is a fair challenge. The Agadir warehouse is not a retail site — we should be precise about that. Its purpose is narrow: to prove the physical installation, the ONEE grid connection process, and the O&M operating rhythm under Law 82-21 before we approach a retailer. The unit economics on a logistics warehouse are actually less favourable than retail because energy consumption is lower and less predictable — so if the model works there, it works more strongly in retail. The commercial validation — proving that a retail procurement team will sign a PPA — comes from the anchor retailer conversations we run in parallel from month zero. The warehouse proves the technical and regulatory model. Retail conversations prove the commercial model. We need both, and we run both simultaneously."

Q: "How solid is the Agadir pilot really?"

A: "It is a direct relationship with the site owner — not a cold lead. The site is actively exploring photovoltaic installation and feasibility is the next funded step. We are not claiming a signed contract — we are claiming a warm-start route that lets us prove the model before approaching retail chains. The milestone before Series A is two follow-on sites signed, not just the pilot live. One warm lead gets us started. The financial model takes over from there."

Q: "You carry all the capex. What happens if a client just stops paying after year three?"

A: "We own the asset. We can disconnect it. The PPA is a contracted obligation backed by Law 82-21, not a gentleman's agreement. Beyond the legal position, there is no rational commercial reason for a client to default — we are always their cheapest power option. Their alternative is to pay the grid more. If they somehow defaulted, we remove the panels and redeploy them to the next site. The asset is the protection."

Q: "Does your 3% PPA escalator erode the customer savings over time?"

A: "No — and we have the data to support that. Our 3% escalator is above Morocco's 10-year CPI average of 2%. Electricity prices specifically have risen 5 to 7% annually per BloombergNEF data. VAT on grid power is increasing from 14% to 20% between 2024 and 2026 under the Finance Act — that is a confirmed policy fact already in legislation. So the customer saves more every year relative to the grid, not less. The escalator protects our revenue without eroding their proposition."

Q: "Why not have customers or landlords contribute some capex to make this more capital efficient?"

A: "The moment a client puts money in, they want ownership and control, and the sales cycle triples in length. Our entire commercial advantage is simplicity — zero upfront, cheaper bill, nothing to own or manage. The second we ask them to contribute, we become a construction project negotiation, not an energy contract. This is precisely why every other model in Morocco has failed to scale. The value proposition only works if we carry everything. That is also what creates the 20-year recurring revenue stream — because we own the asset, we collect the revenue."

Q: "You say the model becomes self-funding at 17 to 20 sites. Walk me through that."

A: "Each site generates roughly £87K in annual PPA revenue at 86% gross margin. After debt service of around £22K per year, levered cash flow per site is approximately £48K in year one, rising with the PPA escalator. At 17 sites, cumulative operating cash flow is sufficient to cover both company overheads and the £79K equity injection for each new site — we no longer need to raise external equity to open sites. The green bank still funds 70% of each build, but our own cash flow covers the 30%. That is the crossover point. Series A bridges us there."

Q: "86% gross margin. That is a software margin on a hardware business. What are you not counting?"

A: "The 86% is the operating margin — revenue minus O&M at 12% and insurance at 1.5%. It excludes debt service, depreciation, and corporate overhead. After debt service in year one, site net income is around £41K on a £260K asset. That is still strong. The margin is high because the cost base is almost entirely variable — it scales as a fixed percentage of revenue, not as a fixed cost. Contracted infrastructure assets with long-duration revenue streams do trade at high operating margins. Toll roads, fibre networks, utility scale solar — the same pattern. The 86% is not a mistake."

Q: "What is your sensitivity to capex overruns?"

A: "The model is stress-tested at three capex levels: £400 per kilowatt which is the SOLAROC benchmark, £1,023 per kilowatt which is our base case including carport premium and volume discount, and £1,184 per kilowatt which is the conservative DD-corrected figure. At the most conservative capex assumption, levered IRR stays above 10%. PPA discount is also sensitivity-tested at 15%, 20% and 25% below grid. Base case uses 20%. Even in the worst combined scenario — highest capex, lowest PPA discount — the business still generates positive returns. We built the model to survive stress, not just to look good at base case."

Q: "Why a convertible note and not a straightforward equity round?"

A: "We do not have enough traction to justify a fixed valuation negotiation. The note lets us close quickly, reward early investors with the cap, and have the proper valuation conversation at Series A when we have a live asset, contracted revenue, and real data. The £2.6M cap protects the investor — they convert at a lower price than Series A investors regardless of how the company is valued at that round. It is the standard structure for pre-revenue infrastructure seed rounds where the asset value will be clear at the next stage but is hard to argue today."

Q: "Do you need to raise money every time you want to add a site?"

A: "Only in the early stages, and only the 30% equity slice — £79K per site. The 70% debt is drawn from a green bank against the asset each time, so we are never raising the full build cost from equity investors. By year three, operating cash flows from existing sites cover the equity tranche for new sites. We are not perpetually diluting — we are buying ourselves out of that dependency as fast as cash flows allow. Seed gets us to the pilot. Series A gets us to 20 sites. After that, the portfolio funds its own growth."

Q: "You claim zero structured competitors. But industrial PPA providers exist in Morocco. Why can't they just move into the retail segment?"

A: "Industrial PPA providers focus on large bespoke deals — minimum one megawatt, six to twelve month procurement cycles, bespoke negotiation for every site. They do not do retail contracts, they do not work on leased sites, and they do not have a standardised multi-site framework. Threat high on our competition slide means they could theoretically adapt — not that they currently compete with us. The retail segment requires a completely different commercial model: standardised contracts, shorter sales cycles, smaller sites, different financing structures. We built specifically for that gap. An industrial provider entering retail would be starting from scratch in a segment they have never operated in."

Q: "What stops a well-capitalised European solar company entering Morocco and doing exactly this?"

A: "First, Law 82-21 is new — no one has built the operational playbook yet, and that playbook is what we are building with the pilot. Second, Youssef is Moroccan, French and Arabic fluent — the commercial relationships required to close a PPA with a Moroccan retail chain take years to build and cannot be

replicated by a foreign entrant writing cheques. Third, by the time a competitor enters, we have signed PPAs, contracted revenue, and an operational asset. They start from zero in a relationship-driven market. First mover advantage in this specific context is real."

Q: "You are five graduates with no track record in infrastructure, project finance, or the Moroccan energy sector. Why should anyone give you £420K?"

A: "We are not asking anyone to trust our experience — we are asking them to trust the structure. Each founder owns one critical execution risk: commercial access, capital structure, technical delivery, regulatory coordination, and partnerships. Where we lack operational depth, we bring in advisors who have it — EPC contractors, Moroccan legal counsel, project finance specialists. Youssef is Moroccan with existing commercial relationships on the ground. Fariha has built the financial model and SPV architecture. The £420K funds the first 18 months, at the end of which we have a live asset and a trackable record. The ask is to fund the proof, not to fund blind faith."

Q: "What happens to the business if Youssef — your only Moroccan founder — leaves?"

A: "Youssef's relationships are an asset but the business is not built on one person. The commercial pipeline he opens gets documented, contracted, and institutionalised — a PPA is a legal document that does not walk out with a founder. Vesting schedules and shareholder agreements are part of the month zero legal spend. We structured the team around execution risks, not individuals. If Youssef left, the commercial workstream slows — it does not stop. The asset-backed nature of the business means value sits in the sites and the contracts, not in any single founder."

Q: "Your TAM is £260M but your 5-year target is 47 sites — roughly £12M of installation value. That is 5% of TAM. Why is your addressable market capture so small?"

A: "47 sites is our 5-year rollout target, not our ceiling. We are being conservative because this is infrastructure — each site requires feasibility, regulatory approval, EPC selection, and commissioning. 47 sites at £87K annual revenue generates £4.2M ARR, which is the number that matters for valuation at exit. The TAM validates the opportunity size. The SOM reflects what we can actually execute in five years without cutting corners on quality. Capturing 5% of a £260M market and building £4.2M of contracted ARR is not a small outcome — at 4.5× revenue that is a £19M enterprise value."

Q: "What if Morocco's grid tariffs stayed flat or fell? Your whole proposition depends on the grid being expensive."

A: "The customer is already saving from day one — we set the PPA rate below whatever the grid charges at signing. Even if tariffs flatlined, the client is still better off with us than the grid for the life of the contract. Our 3% escalator would only become a problem if grid tariffs fell significantly and stayed below our escalating PPA rate consistently over 20 years. Morocco imports 90% of its energy — structurally, tariffs are more likely to rise than fall. And the 2026 VAT increase to 20% is already in legislation. That alone widens the gap by several percentage points in the first year."

Q: "The SR500 programme and Law 82-21 are policy tailwinds. What happens if policy changes?"

A: "Law 82-21 is enacted legislation, not a programme that can be cancelled by a change in minister. The PPA structure is backed by the law — existing signed PPAs would be protected under contract law even if the regulatory framework changed. SR500 is a government programme and could theoretically be wound down, but our business does not depend on SR500 — it depends on the ability to sign PPAs, which Law 82-21 enshrines. The policy risk is real but it is the foundational law that matters, not the programme."

Plan Draft Akilesh (Working on Visuaks)

3. Sector Analysis Including Forward-Looking Outlook

3.1 Macro Context

Morocco is in an unusual position when it comes to the global energy landscape, as they import 90 percent of its primary energy supply, unlike its regional neighbors. This makes them dependent on imports for the majority of their energy supply. This structural vulnerability has been felt by Moroccan businesses since 2008, but the 2022 energy crisis has further more elevated the need for renewable energy. This has made the corporates to push for sustainability, which has led to the focus on sustained political commitment to renewable energy.

That commitment towards sustainability can also be seen at the highest level of political governance. Morocco launched its first renewable energy law in 2009. Since then, the country has invested consistently and heavily in solar infrastructure, especially in the NOOR complex near Ouarzazate, a concentrated solar power and photovoltaic installations that possess 580 MW of solar energy. This program is a clear visible indication of Morocco's heavy investment and commitment towards renewable energy, making it one of the biggest ambassadors of renewable energy in the African continent. The NOOR program demonstrates that Morocco could finance, build and operate large-scale solar assets within its regulatory environment.

Currently, Morocco's target is to possess 52% installed renewable electricity capacity by 2030 and push to 705 by 2050. This is simply not a political aspiration. This is embedded in Morocco's Nationally Determined Contributions under the Paris Agreement and backed by dedicated institutional infrastructure, including the Moroccan Agency for Sustainable Energy (MASEN) (IRENA, 2024). However, there is a crucial gap in the state led energy initiatives. Through the government's initiatives, the utility-scale solar has grown significantly but the commercial and industrial segment has been neglected. There is a huge gap and opportunity in distributed self-generation in the commercial sector.

The NOOR model requires large panels, a huge investment, and grid-level interconnection. This model does not suit a 200-space retail car park in Casablanca or a logistics hub in Agadir. This difference between the current model and the actual requirements for the unserved sectors is the gap in Morocco's energy transition. This is not for lack of sunlight or policy intent, but due to structural barriers in financing, ownership, and utility-focused frameworks, which do not address the needs of the commercial and logistical sector.

3.2 Regulatory Environment

Prior to Law 82-21 in 2023, there was no lawful means for a company to generate electricity on a commercial site and sell it to the site operator under a structured contract. This new Law represents the legal framework for distributed self-generation under third-party Power Purchase Agreements in Morocco. Law 82-21 consists of three specific provisions that collectively make SunPark's model legally possible: a self-generation framework permitting installations for on-site consumption, simplified licensing procedures for installations below 5 MW (removing the

multi-year approval processes that previously stalled commercial-scale projects), and surplus injection rights allowing excess generation to feed back into the ONEE-managed grid (Ministère de la Transition Énergétique, 2023). These provisions pave way for a 20 year PPA commitment that has been impossible previously.

The Office National de l'Électricité et de l'Eau Potable (ONEE) possess monopoly control over Morocco's energy infrastructure. There is a real critical barrier for any distributed energy project. For every project, ONEE's approval is mandatory. This is a significant barrier as it requires eight to twelve weeks for approval but also requires proactive engagement from early stages. This serves as an advantage for Sunpark as it requires any foreign energy service company entering Morocco to face the relationship heavy approval process. This creates a barrier to entry which is the local knowledge and relationships within the ONEE which Sunpark has already invested heavily from its early stages. This regulatory environment creates initial friction for Sunpark but also acts as an important structural barrier protecting Sunpark from undifferentiated early market entrants.

The Morocco-Switzerland SR500 programme, launched in 2024 further increases the momentum for distributed commercial segment. This programme targets 500 MW of commercial nad solar capacity by 2030. The SR500 is a clear indicator of the Moroccan government that the commercial segment has become a priority for the government. The IFC and Crédit du Maroc green SME lending facility is a \$100 million green finance instrument announced in 2024 targeting commercial solar projects. The programs combine in a institutional environment that significantly de-risks SunPark's project financing assumptions. Draft amendments to Law 82-21 are currently under consultation, which shows a potential expansion of licensing simplifications and clearer grid injection tariff structures. The regulatory amendments and the initiatives of the government is clearly positive for SunPark and distributed energy distribution in commercial sector.

3.3 Market Sizing and Outlook

SunPark's addressable market has been sized with a bottom-up approach. With this approach, the market sizing starts working from the total available commercial sites in the country to the subsets of sites which are technically and commercially suitable and feasible for solar carport installation. This approach is preferred over estimating market share from top-down market data because it is based on real-world evidence, such as physical constraints and existing contracts, rather than broad market assumptions from market data.

The Market sizing begins with an estimated 4,500 commercial premises across Morocco's retail, logistics, hospitality and office sectors derived from commercial property registers and also cross-referenced with satellite site counting. the analysis applies four sequential filters.

The first filter removes sites with less than 100 accessible parking spots which reduces the site pool from 4500 to 1800. Second, structural and grid-proximity filters remove sites where carport installation is physically impractical or where the distance from the ONEE grid connection point exceeds 200 metres. 600 sites have not passed this test which leaves the total to 1200 sites.

Third filter excludes sites where the landlord has already entered a different solar contract.

Finally, applying a minimum energy threshold equivalent to approximately 300 kWp of installed

capacity, to ensure the £260,000 installation is financially justified, yields a final addressable market of approximately 1,000 viable commercial sites.

At SunPark's per-site installation cost of £260,000, this 1,000-site market represents a total addressable market of approximately £260 million. The numbers stated are in British Pounds for consistency with investors and academic reporting convenience. All underlying commercial assumptions use Moroccan Dirham converted at a constant exchange rate, with currency sensitivity analysis conducted separately.

Morocco's solar market has grown at an estimated annual rate of approximately 18.9% over the past five years, a figure consistent with IRENA's projections for North African solar markets through 2030 (IRENA, 2024; Grand View Research, 2025). With these growth prediction , three scenarios are important to observe for SunPark;s planning and timeline modelling.

Base case (15% of annual capacity additions in the commercial segment): Assumption of steady implementation of Law 82-21 licensing procedures, moderate commercial adoption driven by rising tariffs, and a C&I solar segment growing in line with overall market CAGR. This is the expected scenario where SunPark reaches 20 sites and Series A readiness by Year 3.

Upside case (25%+ of capacity additions): Assumption of a faster regulatory implementation than expected, earlier green bank debt deployment under the IFC–Crédit du Maroc facility, and SR500 programme acceleration. Commercial adoption exceeds projected conversion rates. In this best-case scenario, SunPark could reach 28 sites within the same timeframe.

Downside case (sub-8% of capacity additions): Assumes ONEE approval timelines exceed twelve weeks, commercial retail procurement cycles prove to be longer than modelled, and green bank debt is unavailable on assumed terms. Breakeven is delayed to Year 3; Series A readiness will be pushed to Month 24. It is crucial for SunPark to plan to the potential of regulatory or commercial hurdles to ensure sustainable business operations in unfavourable business environments.

3.4 Theoretical Framework

DiMaggio and Powell (1983) argue that organisations within an institutional field converge through three pressures: coercive (legal mandates), normative (professional expectations), and mimetic (imitation of peers under uncertainty). Morocco's commercial solar sector currently mimics all three pressures discussed. Law 82-21 is the coercive mechanism. prior to this law, the legal basis for a third-party PPA on a commercial site did not exist. SR500 is the normative mechanism. Transforming commercial solar from niche experiment to mainstream expectation. What remains absent is mimetic pressure, which requires a visible reference: one operational retail carport that procurement teams across the sector can point to. SunPark's Agadir pilot is that reference.

Geels (2002) segments energy transitions across three levels: the landscape (climate targets and energy security), the regime (dominant infrastructure and incumbent practices), and the niche (emergent alternatives building traction at the margins). In Morocco, all three levels are in practice. Climate commitments at the landscape level, Law 82-21 and rising tariffs destabilising the ONEE-anchored regime, distributed solar momentum. Transitions accelerate when niche innovations breach the regime before it re-stabilises. SunPark is operating at that boundary.

Both frameworks indicate the same thing: timing. The window opened after Law 81-21. The one factor missing is mimetic pressure, which is the tendency to adopt to peer's innovation. This shows that the first-mover value lies not only in revenue but in establishing the reference installations and contractual relationships that become significant barriers for followers. SunPark is entering at the moment where the first mover advantage is significant and structurally important. The institutional transformation has created a new category possible but SunPark is the first mover before any competitor has built the reference asset that drives adoption.

9. Competitive Analysis

9.1 Competitive Landscape Overview

The Moroccan solar sector is competitive, but the current competitors do not compete in the Market SunPark addresses. Morocco has PPA providers, and some commercial sites have their own energy program. But SunPark is an energy-as-a-Service company. Sunpark is an entity that finances, owns, operates and contracts solar infrastructure across multiple leased commercial sites under a standardised PPA. SunPark's competitors' research shows that SunPark doesn't have a direct competitor yet, as the model hasn't been regulatory feasible until April 2026, when Law 82-21 implementing decree was officially published. There are four categories of adjacent competitors, each with its own capabilities and with distinct structural gaps. Sunpark doesn't compete in an existing market, but it is creating a new category.

9.2 Detailed Competitor Analysis

Local EPC Installers (~50 firms).

There are around 50 local EPC installers across Morocco, ranging from small-scale regional contractors to national-level mid-sized firms. In this model, EPC installers own the procurement, installation, and grid connection aspects of solar installation and do not address financing, ownership, or long-term operations. Every project requires the customer to fund and own the asset. Contracts are one-off construction agreements, not 20-year energy contracts. EPC installers do not operate on leased commercial premises. The split-incentive problem between tenant and landlord sits outside their model entirely. For a retailer who wants cheaper power without capital outlay, an EPC installer model is not feasible.

Industrial PPA Providers.

Industrial PPC providers are mostly international and offer PPA structured solar programs in Morocco. They focus on large scale industrial sites such as manufacturers, mining operations, large single-site consumers above one megawatt. They do not operate on a smaller multi-site framework that SunPark targets as it is outside the scope of their business model. This model is built around one large customer at a time. This model does not translate to a 200-space supermarket car park, and no industrial PPA provider has attempted to make it do so.

In-house / Captive Programmes.

There are a few larger retailers in Morocco that possess an In-house solar team. This category is the clear potential competitor among adjacent competitors. There are three structural features in this model that limit the scale at which it grows as a threat to SunPark. First, it requires the rare alignment of the goal and objectives for the retailer and landlord to cooperate and develop solar assets. Second, it requires the property partner to build solar development capability, a non-core investment most REITs and landlords have no incentive to invest in. Third, in-house programs validate SunPark's assumptions, and they confirm retailers want cheaper power from car parks. SunPark offers that outcome without the capital, the operational burden, or the internal capability requirement.

Foreign EaaS Entrants.

There are no active international Energy-as-a-service competitors in Morocco. There are barriers to entry with local relationships and understanding. However, the risk of competition increases from 2027 onwards as the market becomes legible to international capital, but near-term entry remains unlikely given the operational and relational barriers.

9.3 Porter's Five Forces Analysis

Porter's Five Forces Analysis, when applied to Morocco's commercial solar segment shows that the current conditions are favourable for SunPark but the market dynamics become more competitive over time.

Threat of new entrants: Medium–High. In the commercial solar segment, capital and technical capacity are not the barriers to entry. The real barriers are Law 82-21 operational knowledge, regulatory support, ONEE relationships and local PPA portfolio. Sunpark has the distinct first mover advantage under the new Law 82-21 with the accumulation of contracted assets and institutional relationships that cannot be replicated quickly.

Supplier bargaining power: Low. Tier-1 monocrystalline panels are globally commoditised. There are large numbers of EPC contractors in Morocco at different scales and the solar supplier market is competitive locally. No suppliers possess meaningful pricing leverage.

Buyer bargaining power: Medium. The switching costs in retailers have the ability to negotiate on tariff and terms but the switching costs are very high. the infrastructure is physically embedded, and PPA termination carries contractual penalties. Negotiation power shifts progressively toward SunPark as the portfolio scales.

Threat of substitutes: Low. The primary substitute is Morocco's national grid. The national grid do not possess any meaningful threat for SunPark as Grid prices are significantly higher than SunPark's energy pricing. Grid prices are not expected to decrease as Morocco's 90% import dependency makes it structurally infeasible.

Competitive rivalry: Low, intensifying. Currently minimal and will intensify between 2027 and 2030 as SR500 matures and the market attracts international operators. There is an estimated 18 month window in which SunPark can operate without direct competitors.

9.4 Strategic Positioning

SunPark's business model and strategic positioning is unique and deliberate. SunPark is not a solar company. It is a retail energy contract company. The distinction matters because it redefines what a competitor would need to replicate. Solar panels are commodities. Standardised retail PPAs on leased Moroccan commercial sites, backed by Law 82-21 operational knowledge and an active installation portfolio are distinct differentiators that takes time to replica which gives Sunpark the time it requires to acquire its first few clients and build a local portfolio.

SunPark's positioning is based on four capabilities working together. It operates on leased sites completely solving the ownership problem that stops solar projects from happening. With SunPark, clients do not have any capital or operational burden. One negotiation can cover a customer's entire property portfolio. the SunPark business model has been built inside the new Law 82-21, accumulating regulatory and contractual knowledge a late entrant would take significant time to reconstruct.

9.5 Theoretical Framework: Porter's Generic Strategies

Porter (1985) identifies three generic strategic positions: cost leadership, differentiation, and focus. SunPark pursues focused differentiation. A deliberately narrow segment (commercial retail solar in Morocco) with a genuinely differentiated proposition (PPA financing, standardised contracts, multi-site capability on leased sites). The focus is the defence. Replicating this position requires segment-specific knowledge and Moroccan retail procurement cycles, ONEE processes, leased-site contract structures — that a generalist entrant, however well-capitalised, would take years to build.
